The correct internal surface transport coefficients modelling in the complex models of the heat, air and moisture transport in a building concerns the local thermal balance of the air boundary layer near the internal surfaces.

The heat transfer between a solid wall and an air is defined by the temperature difference and the convective heat transfer coefficients.

The new experimental optical non-invasive method that does not influence the conditions in the boundary layer has been used in this work.

The combination of the experimental data and CFD numerical simulations were used to evaluate of the influence of ambient air speed on convective heat transfer coefficient.
Scheme of the experiment
Experiment

**Experimental apparatus**

- **Laser diode**: 10mW/650nm
- **Double photodiode**
Experiment

Experimental apparatus

- gypsum board 12.5 mm
- heating foil max 197W/m²
- gypsum board 12.5 mm
- aluminium plate 4 mm
- heating foil max 197W/m²
- aluminium plate 4 mm
Numerical simulation

Simulation model

- OpenFoam CFD v.1.2 software package,
- laminar convective regime,
- Boussinesq approximation for natural convection,
- Structural grid with 1mm control volume thickness near wall,
- 1.2mil. control volumes.
Results

Measured temperature gradient profiles in comparison with CFD simulation of natural convection regime

\[
\Delta T = 12.2 \text{ K} \\
z = 0.25 \text{ m} \\
Gr = 3.105 \times 10^7
\]

\[
\Delta T = 1.5 \text{ K} \\
z = 0.10 \text{ m} \\
Gr = 2.398 \times 10^5
\]
Results

Approximation of the measured temperature gradient profile

Gauss regression

\[
\frac{d\theta}{dy} = a + b \cdot e^{-\left(\frac{y-c}{d}\right)^2}
\]

Temperature profile

\[
\theta(y) = \int \frac{d\theta}{dy} dy = a \cdot y + \frac{1}{2} \pi^2 \cdot d \cdot \text{erf}\left(\frac{y-c}{d}\right) \cdot b + C
\]

Integration constant

\[
C = \theta_{si} + \frac{1}{2} \pi^2 \cdot d \cdot \text{erf}\left(-\frac{c}{d}\right) \cdot b
\]
Results

Dimensionless temperature profiles

$\Delta T = 12.2 \text{ K}, \ z = 0.25 \text{ m}, \ Gr = 3.105E7$

Ostrach´s approach

Bejan´s approach

$T^* = \frac{T - T_\infty}{T_{\text{sat}} - T_\infty}$

$\eta = \frac{y}{z} \left( \frac{Gr_y}{4} \right)^{1/4}$
Results

Dimensionless temperature profiles

\[ \Delta T = 1.5 \text{ K}, \ z = 0.10 \text{ m}, \ Gr=2.398\text{E}5 \]
Results

Local Nusselt number vs. Local Rayleigh number

\[ \text{Nu}(x) = 0.387(Ra_x)^{0.25} \] (Ostrach 1953)
Results

Approximation of temperature gradient and near wall temperature using initial air flow velocity

\[ \Delta T = 12.2 \text{ K}, \ z = 0.25 \text{ m}, \ Gr = 3.105\text{E7} \]
Results

Approximation of temperature gradient and near wall temperature using initial air flow velocity

\[ \Delta T = 1.5 \text{ K}, \ z = 0.10 \text{ m}, \ Gr=2.398\times10^5 \]
**Results**

**Calculated vertical profile of convective heat transfer coefficient**

\[ \Delta T = 12.2 \text{ K} \]
\[ z = 0.25 \text{ m} \]
\[ Gr = 3.105 \times 10^7 \]

\[ \Delta T = 1.5 \text{ K} \]
\[ z = 0.10 \text{ m} \]
\[ Gr=2.398 \times 10^5 \]
Conclusion

- Experimental optical non-invasive method that does not influence the conditions in the boundary layer has been used.

- At the higher temperature difference conditions the better coincidence with the data of CFD modelling has been observed and on the contrary, at smaller temperature differences the experimental values differ noticeably.

- Influence of the ambient air velocity on the convective heat transfer coefficient at low temperature differences had shown as significant.

- Dominant influence of the ambient air speed on the local values of convective heat transfer coefficient was obtained mainly at the bottom part of the plate.

- The proposed approach of experimental/numerical analysis of the boundary layer has shown its usefulness and effectiveness for the study of the boundary layer even at the conditions at very low temperature contrast of only a few degrees.
